APPARATUS AND METHOD PROVIDING UNIFIED NETWORK MANAGEMENT

CROSS-REFERENCE TO RELATED APPLICATIONS; PRIORITY CLAIM

This application claims the benefit under 35 U.S.C. 120 as a Continuation of application Ser. No. 11/012,884, filed Dec. 14, 2004, which claims the benefit of provisional application 60/481,788, filed Dec. 14, 2003, the entire contents of which are hereby incorporated by reference for all purposes as if fully set forth herein.

FIELD OF THE INVENTION

The present invention generally relates to computer network management. The invention relates more specifically to methods for managing networks using representations of networks.

BACKGROUND

The approaches described in this section could be pursued, but are not necessarily approaches that have been previously conceived or pursued. Therefore, unless otherwise indicated herein, the approaches described in this section are not prior art to the claims in this application and are not admitted to be prior art by inclusion in this section.

A typical computer network consists of various devices such as routers, switches, wireless access points, firewalls, etc. FIG. 1 illustrates an example network that includes such elements.

A typical network device provides a command interface that is accessible using the telnet protocol, a secure shell (SSH) connection, or serial port interface to create, update, retrieve and store management information relating to the device. A network management station (NMS) can deliver commands through such an interface to provide a higher level or enhanced management capability to the network operator or administrator. Each device in the network can be managed individually by one or more than one network management stations.

The management aspects of a device are defined as mechanisms available on the device to add, delete, modify and monitor the behavior of a device as required by the network operator to achieve the required operation on the device. The management aspects of each device are obtained by means of Simple Network Management Protocol (SNMP), Telnet, Secure Shell (SSH) and other access methods provided by the individual devices.

However, management of large networks is cumbersome, error-prone and time-consuming using current approaches. For example, assume that a large network comprises dozens of network devices of the same type, all of which require the same configuration change. In this context, applying the same change to each device individually is time-consuming and error-prone.

Further, for management purposes, applying a particular configuration command or query to all devices that share a particular characteristic may be useful. Prior systems have offered the ability to display the features or characteristics of a particular device or groups of devices. However, in the past there has been no good way to apply the same command to all devices in a group or view.

Therefore, there is a need for a better way to manage a network to overcome the foregoing problems.

2

BRIEF DESCRIPTION OF THE DRAWINGS

The present invention is illustrated by way of example, and not by way of limitation, in the figures of the accompanying drawings and in which like reference numerals refer to similar elements and in which:

FIG. 1 is a block diagram of a typical network arrangement in which an embodiment may be implemented;

FIG. 2 is a block diagram of unified network management framework according to some embodiments;

FIG. 3 is a representation of entire network as a tree;

FIG. 4 is a block diagram of command flow from network operator to the device through a unified network management (UNM) framework;

FIG. 5 is an example of navigation using UNM;

FIG. 6 is an example of viewing alarms using UNM;

FIG. 7 is a block diagram that illustrates a computer system upon which an embodiment may be implemented;

FIG. 8 is a block diagram of an auto-learner framework according to some embodiments;

FIG. 9 is a flow diagram of an auto-learning process.

DETAILED DESCRIPTION

An apparatus and system providing unified network management is described. In the following description, for the purposes of explanation, numerous specific details are set forth in order to provide a thorough understanding of the present invention. It will be apparent, however, to one skilled in the art that the present invention may be practiced without these specific details. In other instances, well-known structures and devices are shown in block diagram form in order to avoid unnecessarily obscuring the present invention.

Embodiments are described herein according to the following outline:

1.0 General Overview

2.0 Structural And Functional Overview

3.0 Implementation Mechanisms—Hardware Overview

4.0 Extensions and Alternatives

1.0 GENERAL OVERVIEW

The needs identified in the foregoing Background, and other needs and objects that will become apparent from the following description, are achieved in the present invention, which comprises, in one aspect, a method of unified network management comprising the machine-implemented steps of creating and storing a logical tree representation of a network, wherein the network comprises one or more network devices each having one or more characteristics, wherein a root node of the tree represents the entire network, wherein leaf nodes of the tree represent the network devices, wherein one or more intermediate nodes of the tree represent one or more groups of network devices having common characteristics; receiving a first command that selects any of the entire network, the groups, or the devices; receiving one second command that specifies a single management operation for application to each network device in the selected network, groups, or devices; automatically performing the specified management operation on each network device in the selected network, groups, or devices.

In one feature, the management operation comprises displaying a list of devices that are contained in the entire network or the selected group. In another feature, the management operation comprises configuring a plurality of interfaces that are implemented by a plurality of selected devices. In another feature, the management operation com-

prises configuring a plurality of interfaces that are implemented by all devices in a selected group.

In yet another feature, the management operation comprises displaying one or more alarms that are generated by all devices in a selected group. In still another feature, the management operation comprises displaying one or more events that are generated by all devices in a selected group. According to another feature, the intermediate nodes of the tree represent one or more groups of network devices, wherein the grouped network devices are similar but not identical in device type. In still another feature, a leaf node of the tree representing a device further comprises a sub-tree that represents a file system of the device.

According to another feature, the second command specifies one of a plurality of common management aspects of each device in the selected network, group or devices. In another feature, receiving the first command comprises receiving a plurality of commands that navigate the tree from root to a leaf node or intermediate node.

In other aspects, the invention encompasses a computer apparatus and a computer-readable medium configured to carry out the foregoing steps.

2.0 STRUCTURAL AND FUNCTIONAL OVERVIEW

An example embodiment is now described with reference to FIG. 2, FIG. 3, FIG. 4, FIG. 5, and FIG. 6. FIG. 2 is a block diagram of unified network management framework according to some embodiments; FIG. 3 is a representation of entire network as a tree; FIG. 4 is a block diagram of command flow from network operator to the device through unified network management (UNM) framework; FIG. 5 is an example of navigation using UNM; and FIG. 6 is an example of viewing alarms using UNM.

In one embodiment, a Unified Network Management (UNM) framework has the structure depicted in FIG. 2. A managed network may comprise, for example, three devices designated Device A, Device B, and Device C. Each of the devices comprises non-volatile random-access memory (NVRAM), non-volatile flash memory ("Flash"), and two interfaces designated Interface 1, Interface 2. According to an embodiment, information representing the physical elements of each device in the network is mapped to the UNM and represented in the UNM. For example, the UNM comprises an NVRAM data structure that stores information representing the NVRAM of each of Device A, Device B, and Device C. Further, the UNM has a Flash data structure that represents the flash memory of Device A, Device B, and Device C. The UNM further comprises an interface data structure that represents interfaces of each of the devices.

A network device in the managed network may host the UNM. Alternatively, the UNM is hosted in a workstation, server, or other device that is communicatively coupled to the managed network.

In this arrangement, the UNM represents the entire network or subset of the network as if the network or subset comprises a single device. However, all management aspects of each device are made available to the network operator by the UNM framework. For example, a network administrator can get or set values relating to the external interfaces, commands and control characteristics of each device at the UNM framework as if these interfaces and commands are provided by the device that is implementing the UNM framework. In addition to providing the management aspects of the individual devices, UNM also provides network level view of these devices. Two or more devices of similar or different

types of devices can be grouped and their common management aspects can be represented as a single device to the operator.

The UNM framework of FIG. 2 represents the entire network as a single device by providing and implementing the management aspects of each individual device that is under its control. The UNM framework represents one device, one or more external interfaces, and one or more commands that are applicable on the interfaces. Management aspects of individual devices in the managed network are exposed to the network operator by means of interfaces and commands. In particular, the interfaces, commands, and characteristics of each device are exposed at the UNM framework, as if these interfaces and commands are provided by the actual framework on the device.

More than one device can implement a UNM framework as shown in FIG. 2 to represent the entire network. A single network can be segmented into multiple networks, and each of the network segments can be managed separately by a different device implementing the UNM framework. Further, the devices implementing the UNM framework can be managed by a single device implementing UNM framework in a clustered fashion.

In one embodiment, the UNM framework implements management aspects of each managed device by any of several means, such as Simple Network Management Protocol (SNMP), TELNET, Secure Shell (SSH) and various other control methods provided by the individual devices.

In one embodiment, the UNM framework is communicatively coupled to a command knowledge base. The command knowledge base describes the command syntax that a particular managed device uses. For example, an embodiment may use a command knowledge base as described in co-pending application Ser. No. 11/012,885, filed Dec. 14, 2004, "METHOD AND SYSTEM FOR AUTOMATICALLY DETERMINING COMMANDS FOR A NETWORK ELEMENT," inventors Krishnam Datla et al., now U.S. Pat. No. 8,190,723, the entire contents of which is hereby incorporated by reference as if fully set forth herein.

The knowledge base may be different for different types of devices, and for different versions of operating system for the same type of device. Therefore, when a user selects multiple devices for applying one management operation, the UNM framework uses a command base containing only commands that are common to all the selected devices. This common command base is built when it is needed, or in real time, before any management operations are invoked. The common command database is used for all the management operations on the selected group of devices.

In an embodiment, the UNM framework provides any or all of the following methods to the network operator to manage the entire network as a single device.

1. According to one feature, an entire managed network is represented as a tree structure in which each device is represented by a node of the tree. Referring now to FIG. 3, a tree representation of a network may comprise a root node representing the entire network. The tree may further comprise one or more group nodes that represent groups of devices. For example, in FIG. 3, intermediate nodes representing group nodes are designated Group A, Group B, Group C, Group D. The tree representation may further comprise leaf nodes that represent network devices, as shown in FIG. 3.

To interoperate with a network device, the NMS must have knowledge of what commands the device supports, so that the NMS can deliver commands that are compatible with the device's command interface and that produce desired results.

5

Referring now to FIG. 8, according to one embodiment, an auto-learner framework 802 comprises device command syntax knowledge 804, a seed command 806, special case handling logic 808, a request generator 810, and a response handler 812. An embodiment may implement framework 802 in one or more computer programs or other software elements, firmware, or any combination thereof. Framework 802 is coupled to or includes a knowledge base 816, which provides a repository for storing information that defines commands that a network element 820 supports. Framework 802 is coupled, directly or indirectly through one or more networks, to network element 820.

A seed command 806 defines a particular device command which, when sent to network element 820, will cause network element to reply with a list of supported commands.

Special case handling logic 808 provides program code or other software elements for handling exceptions to the general rules that are defined in syntax knowledge 804. Such exceptions may be the same for all devices in a family of devices, or may apply only to the functionality or feature that is being learned at a particular time.

Request generator 810 forms and sends commands or information requests to network element 820. Response handler 812 processes replies that are received from the network element 820 and creates data for storage in the knowledge base 816.

FIG. 9 illustrates an example process in more detail. For purposes of illustrating a clear example, FIG. 9 is described in the context of the system of FIG. 8. However, other embodiments of the techniques of FIG. 9 may be implemented in the context of other systems.

In step 902, a seed command is sent. For example, auto-learner framework 802 sends seed command 806 to network element 820. In step 904, a list of all supported commands for the device is received and stored. For example, network element 820 responds with information defining all commands that it supports. In one embodiment, the seed command 806 is a “help” or “?” command, and in response, the network element provides a list of all commands that are allowed in the then-current context of the network element. Routers, switches, and other network devices from Cisco Systems, Inc., San Jose, Calif., support seed commands of the type just described.

At step 906, the process selects one command in the received list for further processing. Step 906 represents the start of a loop that ends at step 914 and includes steps 909, 910, 912 for determining what parameters the network element requires, uses or defines as part of the selected command. For example, at step 908, the process sends a request for parameters for the selected command. At step 910, the process determines if all parameters for the request have been received, based on receiving and analyzing a response from the network element, as shown by step 909.

If not all the parameters were received for the selected command, then control returns to step 908 and further parameter requests are sent. If all parameters have been received, then at step 912, information defining the selected command is stored.

For example, assume that the network element 820 supports a command named “cmd1” that requires two parameter values to be set, and that the required syntax is “cmd1 parameter1 value1 parameter2 value2.” In one case, step 908 involves sending the request “help cmd1,” and in response, the network element provides a complete listing of parameters and values. In another case, step 908 involves sending an incomplete command and the network element responds by providing a complete listing of parameters and values.

6

In yet another case, step 908 involves sending an incomplete command, and a response from the network element indicates only the next parameter that the command syntax requires. For example, sending a request of the form “cmd1 parameter1” causes the network element to respond indicating that it needs a value of type X. The particular one of the foregoing cases applicable to a particular type of network element may vary according to the vendor of the network element, the operating system, or other factors. The particular one of the foregoing cases applicable to a particular type of network element may be defined, in one embodiment, in syntax knowledge 804.

Requests sent at step 908 might require a literal value for a parameter in order to enable the process of FIG. 9 to determine the next valid parameter for a command. In one embodiment, step 908 involves forming a command that includes valid sample values for any parameters that require specifying a value as a condition to learn the next parameter. For example, to induce a response that defines additional parameters for a command relating to setting parameters on a fast Ethernet interface of a wireless access point, the command must include a valid IP address for the interface. In this example, step 908 involves generating a sample Ethernet interface address to include in the command.

Some commands that some network elements support may allow an unlimited number of parameters and values. Therefore, the approach of FIG. 9 is provided with a mechanism to prevent endless loops. For example, assume that at step 908 and step 909 the following command example and reply are sent and processed, respectively:

```

issc-gw#show ip bgp community ?
<1-4294967295> community number
exact-match Exact match of the communities
local-AS Do not send outside local AS (well-known community)
no-advertise Do not advertise to any peer (well-known community)
no-export Do not export to next AS (well-known community)
| Output modifiers
<cr>
Assume further that after analysis at step 909, the process next sends the command and reply as follows:
issc-gw#show ip bgp community 123 ?
<1-4294967295> community number
exact-match Exact match of the communities
local-AS Do not send outside local AS (well-known community)
no-advertise Do not advertise to any peer (well-known community)
no-export Do not export to next AS (well-known community)
| Output modifiers
<cr>

```

In this case, the same set of parameters and descriptions has been provided by the network element in responses for both commands identifying the “community” node and “<1-4294967295>” node. The second request included “123” as a sample node identifier value and received the same result as when the first request included “community” as a node identifier. Therefore, sending further commands that specify additional nodes will not yield additional useful information, and an unlimited list of parameter values is allowed. Therefore, the process detects an endless loop and discontinues requesting parameters for the current command.

In an embodiment, the presence of a recursive command that will cause an endless loop is detected as follows. First, the

process compares the help command result, which is a list of parameter hints and descriptions, for the current node's parent with the current node's help results. In this context, "node" refers to a data structure in the knowledge base that defines and is associated with a command. If the result information is the same for both nodes, then the process of FIG. 9 considers an unlimited parameter list to exist, and this is represented in the command knowledge base.

At step 914, a test is performed to determine if all commands have been processed. If so, then at step 916, the command knowledge base 916 is created. The command knowledge base 816 may be structured according to any convenient text or binary format.

In one embodiment, the command knowledge base is stored in Extensible Markup Language (XML) format according to the example schema shown in FIG. 4. In operation, an NMS can receive, parse, and use such a command knowledge base.

Using the preceding general process, based on basic command syntax knowledge, an auto-learner framework generates a series of requests and analyzes responses from a network element until all commands are completely learned.

A network device in the managed network also may be represented in the tree representation as an intermediate node, depending on the capabilities or logical connectivity of the device with other devices. Further, if the device has a file system, then the file system can be represented as a sub-tree under the device node.

Additionally, the tree representation may comprise other intermediary nodes that define groups of network elements based on various criteria. One example of such criteria is selecting a group of devices according to the role they play in network. For example, all routers may be represented by one intermediate node. As other examples, all switches, all wireless access points, all wireless access point of certain type X, etc., may be represented by various intermediate nodes.

Using such a representation, the UNM framework enables a network administrator to navigate the entire network in a manner similar to navigating a directory. Further, in one embodiment, the tree representation of a network is implemented using a filesystem, such as the UNIX or LINUX filesystems. A navigation path may proceed from a group of devices to individual devices down to the level of individual files or directories on the device.

Referring now to FIG. 4, an example navigation in a filesystem representation of a network is shown. Starting at the top line, and as indicated by the text in subsequent lines of FIG. 4, the prompt "[network]#" indicates that the operator is interacting with the root node representing the entire network. The operator enters a "dir" or "directory" command; in response, the UNM displays a directory of the/network/node, which includes a "devices/" intermediate node and "groups/" intermediate node.

The operator then navigates to the "devices" group by entering the command "cd devices" meaning "change directory to devices directory." Next in FIG. 4, the operator enters another "dir" command; in response, the UNM displays a list of all devices in the network by name, type, status, and network address.

The operator then moves up to the root node again with the command "cd . . ." The operator moves down the tree to the "groups" node by entering the "cd groups" command. The operator then obtains a list of all currently defined network groups by entering a "dir" command; in response, the UNM provides a group list that indicates the number of devices in each group and the name of each group (AccessPoints, Switches, MyGroup, offline-devices, etc.). The operator then

obtains a list of all devices that are in the AccessPoints group with appropriate "cd" and "dir" commands.

2. According to another feature, the UNM enables an operator to select a group of devices and then access or configure the common management aspects of all the devices in the selected group, as if the operator is interacting with a single device. Referring now to FIG. 5, an example of group selection and interaction is shown. In the first line of FIG. 5, an operator provides an instruction to the UNM with the command "network group AccessPoints." As a result, a group of wireless access point devices named AccessPoints is selected. The operator next enters a "configure" command, which instructs the UNM to enter network configuration mode. The operator then instructs the UNM that the operator wishes to configure all the fast Ethernet interfaces of the devices in the group, with the command "interface all-fast-ethernet". The UNM responds by indicating the number of interfaces in devices in the group that will be affected by subsequent configuration commands. The operator may then enter one or more configuration or other management commands. Thus all selected devices can be configured, modified or monitored as if the user is interacting with a single interface.

3. In another feature, the UNM enables a user to select a device or a group of devices and to then display or receive alarms from the selected group. FIG. 6 shows an example of such interaction with the UNM. Referring to the first line of FIG. 6, a network operator selects a group of wireless access points of a certain type using the command "cd AccessPoints." The operator then displays all devices in that group with the "dir" command.

The operator enters the command "show alarms" to view alarms for the selected devices. In response, the UNM displays a list network alarms, but only the alarms that have been received from the devices in the selected group. Thus, the network operator receives a display of alarms from a plurality of devices, but the network operator is only required to issue one "show alarm" command. Therefore, interaction with the network is greatly simplified. For example, in prior approaches, the operator would have had to connect to each device individually and then enter the "show alarms" command for each device.

The same general approach as described above may be used when the network operator wishes to display alarm information for a single device. Referring again to FIG. 6, the operator next enters the command "network 192.168.1.201," which indicates that the operator wishes to interact only with the device having the specified IP address. The operator then enters a "show alarms" command. In response, the UNM displays alarm information only for the specified device.

4. In yet another feature, the UNM enables an operator to select a device or group of devices to receive events from the selected group. One example is a group wireless access points of certain type X is selected and only the events received from these devices are presented to the network operator as if the events are coming from a single device.

5. In still another feature, the UNM enables an operator to apply a single configuration policy or configuration command to a device or a group of devices. Examples include:

- a. allow firmware-version 10.3.1 for group=AccessPoints
- b. allow firmware-version 9.9.9 for device=192.168.1.1
- c. allow firmware-version 1.1.1 for devicetype=switch

6. In still another feature, the UNM enables a network operator to apply the same commands available on a device to perform a task at the network level so that the command is applied to the all devices selected.

In one embodiment, the UNM implements multiple levels of commands that can be applied to network devices or groups in various ways. At a first level, the UNM provides the same commands that are available on the devices that the UNM manages. At a second level, the UNM provides commands that are common to the selected devices. At a third level, the UNM provides additional commands that are not supported on the devices. In alternate embodiments, the UNM provides other levels with increasing levels of device abstraction than the levels specified above. In these embodiments, the UNM provides flexibility to the network operator through the multiple levels. This enables the network operator to use the same native commands available on the devices operate on the whole network.

The UNM of FIG. 2, tree representation of FIG. 3, and the processes that are illustrated by FIG. 4, FIG. 5, and FIG. 6 may be implemented using one or more computer programs, processes, or other software elements. In other embodiments, an apparatus is provided comprising a device that manages the network and devices in it and allows a network operator to manage the network and devices as a single device. In one feature, the native interface of the devices in the network is made available. In another feature, the same kind of devices in a network are grouped and appear as a single device to the network operator. In yet another feature, common commands across similar devices in a network can be applied by a network operator to all devices using a single command.

In another feature, the entire network is represented as tree where devices, group of devices are represented by nodes according to certain criteria. In a related feature, the file system of the device is represented as sub-tree under the device node. In yet another feature, common management aspects of devices are made available to the network operator, based on a current node that is selected during network tree navigation.

3.0 IMPLEMENTATION MECHANISMS

Hardware Overview

FIG. 7 is a block diagram that illustrates a computer system 500 upon which an embodiment of the invention may be implemented. Computer system 500 includes a bus 502 or other communication mechanism for communicating information, and a processor 504 coupled with bus 502 for processing information. Computer system 500 also includes a main memory 506, such as a random access memory ("RAM") or other dynamic storage device, coupled to bus 502 for storing information and instructions to be executed by processor 504. Main memory 506 also may be used for storing temporary variables or other intermediate information during execution of instructions to be executed by processor 504. Computer system 500 further includes a read only memory ("ROM") 508 or other static storage device coupled to bus 502 for storing static information and instructions for processor 504. A storage device 510, such as a magnetic disk or optical disk, is provided and coupled to bus 502 for storing information and instructions.

Computer system 500 may be coupled via bus 502 to a display 512, such as a cathode ray tube ("CRT"), for displaying information to a computer user. An input device 514, including alphanumeric and other keys, is coupled to bus 502 for communicating information and command selections to processor 504. Another type of user input device is cursor control 516, such as a mouse, trackball, stylus, or cursor direction keys for communicating direction information and command selections to processor 504 and for controlling

cursor movement on display 512. This input device typically has two degrees of freedom in two axes, a first axis (e.g., x) and a second axis (e.g., y), that allows the device to specify positions in a plane.

The invention is related to the use of computer system 500 for unified network management. According to one embodiment of the invention, unified network management is provided by computer system 500 in response to processor 504 executing one or more sequences of one or more instructions contained in main memory 506. Such instructions may be read into main memory 506 from another computer-readable medium, such as storage device 510. Execution of the sequences of instructions contained in main memory 506 causes processor 504 to perform the process steps described herein. In alternative embodiments, hard-wired circuitry may be used in place of or in combination with software instructions to implement the invention. Thus, embodiments of the invention are not limited to any specific combination of hardware circuitry and software.

The term "computer-readable medium" as used herein refers to any medium that participates in providing instructions to processor 504 for execution. Such a medium may take many forms, including but not limited to, non-volatile media, volatile media, and transmission media. Non-volatile media includes, for example, optical or magnetic disks, such as storage device 510. Volatile media includes dynamic memory, such as main memory 506. Transmission media includes coaxial cables, copper wire and fiber optics, including the wires that comprise bus 502. Transmission media can also take the form of acoustic or light waves, such as those generated during radio wave and infrared data communications.

Common forms of computer-readable media include, for example, a floppy disk, a flexible disk, hard disk, magnetic tape, or any other magnetic medium, a CD-ROM, any other optical medium, punchcards, papertape, any other physical medium with patterns of holes, a RAM, a PROM, and EPROM, a FLASH-EPROM, any other memory chip or cartridge, a carrier wave as described hereinafter, or any other medium from which a computer can read.

Various forms of computer readable media may be involved in carrying one or more sequences of one or more instructions to processor 504 for execution. For example, the instructions may initially be carried on a magnetic disk of a remote computer. The remote computer can load the instructions into its dynamic memory and send the instructions over a telephone line using a modem. A modem local to computer system 500 can receive the data on the telephone line and use an infrared transmitter to convert the data to an infrared signal. An infrared detector can receive the data carried in the infrared signal and appropriate circuitry can place the data on bus 502. Bus 502 carries the data to main memory 506, from which processor 504 retrieves and executes the instructions. The instructions received by main memory 506 may optionally be stored on storage device 510 either before or after execution by processor 504.

Computer system 500 also includes a communication interface 518 coupled to bus 502. Communication interface 518 provides a two-way data communication coupling to a network link 520 that is connected to a local network 522. For example, communication interface 518 may be an integrated services digital network ("ISDN") card or a modem to provide a data communication connection to a corresponding type of telephone line. As another example, communication interface 518 may be a local area network ("LAN") card to provide a data communication connection to a compatible LAN. Wireless links may also be implemented. In any such

11

implementation, communication interface **518** sends and receives electrical, electromagnetic or optical signals that carry digital data streams representing various types of information.

Network link **520** typically provides data communication through one or more networks to other data devices. For example, network link **520** may provide a connection through local network **522** to a host computer **524** or to data equipment operated by an Internet Service Provider (“ISP”) **526**. ISP **526** in turn provides data communication services through the worldwide packet data communication network now commonly referred to as the “Internet” **528**. Local network **522** and Internet **528** both use electrical, electromagnetic or optical signals that carry digital data streams. The signals through the various networks and the signals on network link **520** and through communication interface **518**, which carry the digital data to and from computer system **500**, are exemplary forms of carrier waves transporting the information.

Computer system **500** can send messages and receive data, including program code, through the network(s), network link **520** and communication interface **518**. In the Internet example, a server **530** might transmit a requested code for an application program through Internet **528**, ISP **526**, local network **522** and communication interface **518**. In accordance with the invention, one such downloaded application provides for generating diagnoses of network problems as described herein.

The received code may be executed by processor **504** as it is received, and/or stored in storage device **510**, or other non-volatile storage for later execution. In this manner, computer system **500** may obtain application code in the form of a carrier wave.

4.0 EXTENSIONS AND ALTERNATIVES

In the foregoing specification, the invention has been described with reference to specific embodiments thereof. It will, however, be evident that various modifications and changes may be made thereto without departing from the broader spirit and scope of the invention. The specification and drawings are, accordingly, to be regarded in an illustrative rather than a restrictive sense.

What is claimed is:

1. A method, comprising:

at a network management computer, receiving a first command that selects a first group of two or more devices consisting of routers, switches, wireless access points, or firewall devices;

for at least each network device in the first group of devices, sending a seed command, from the network management computer to a particular device;

in response to sending the seed command, receiving a list of commands supported by the particular device;

building a command base of commands in real time by determining a set of commands, wherein each command of the set of commands is associated with all devices in the first group of devices;

exposing the set of commands in the command base that are common to all devices in the first group of devices to enable the network management computer to avoid errors from incompatible commands being individually applied to at least one device in the first group;

receiving a particular command associated with at least one command from the command base;

12

performing at least one management operation associated with the at least one command from the command base on each device in the first group of devices; wherein the management operation is compatible with any device in the first group of devices.

2. The method of claim 1, further comprising selecting a second group of two or more devices; based on the selection, rebuilding the command base of commands for the second group;

performing at least one management operation on each device in the second group.

3. The method of claim 1, wherein the first group of devices is based on a characteristic.

4. The method of claim 3, wherein the characteristic is selected from a group consisting of a device type, a device status, and a device address.

5. The method of claim 1, wherein performing at least one management operation comprises:

receiving a second command;

determining an abstraction level of the second command; based on the abstraction level, implementing the second command through one or more software elements.

6. The method of claim 5, wherein determining involves classifying the second command as a first level command, wherein the first level command is natively available on at least two devices in the first group.

7. The method of claim 6, wherein the management operation is performed on a first device and a second device after determining the second command as a first level command native to the first device, but not native to the second device.

8. The method of claim 5, wherein determining involves classifying the second command as a second level command, wherein the second level command is natively available on at least all devices in the first group.

9. The method of claim 5, wherein determining involves classifying the second command as a third level command, wherein the third level command is not natively available on a device in the first group.

10. The method of claim 1, wherein the commands comprise abstract commands, not available natively on at least one device in the first group, wherein the performing step comprises implementing a command not available natively on at least one device through one or more software elements.

11. A method comprising:

at a network management computer, receiving a first command that selects a group of devices consisting of routers, switches, wireless access points, or firewall devices; for at least each network device in the group of device, sending a seed command, from the network management computer to a particular device;

in response to sending the seed command, receiving a list of commands supported by the particular device;

in response to receiving the first command, building a command base by determining a set of commands, wherein each command of the set of commands is associated with all devices in the group;

exposing the set of commands in the command base that are common to all devices in the group of devices to enable the network management computer to avoid errors from incompatible commands being individually applied to at least one device in the group of devices;

receiving a second command that specifies a management operation for application to each network device in the group;

determining a third command for performing the management operation based on the second command and the command base;

13

automatically executing the third command to perform the management operation on each network device in the group of devices;

wherein the management operation is compatible with any device in the first group of devices.

12. The method of claim **11**, wherein the management operation comprises displaying a list of devices that are contained in the group.

13. The method of claim **11**, wherein the management operation comprises configuring a plurality of interfaces that are implemented by a plurality of selected devices.

14. The method of claim **11**, wherein the group of devices is based on a characteristic.

15. The method of claim **14**, wherein the characteristic is selected from a group consisting of a device type, a device status, and a device address.

16. A system comprising:

at least one network device consisting of a router, a switch, a wireless access point, or a firewall device; and at least one network management station, wherein a network management station comprises a data structure associated with the network device for implementing the steps of:

receiving a first command that selects a group of devices, wherein each device in the group selected by the first command is associated with one or more commands at a plurality of levels, wherein a first level command is included in a native device interface for each device, and a second level command is not natively supported on each device;

based on the selection, building a command base from the group, comprised of second level commands;

wherein each second level command of a set of second level commands is associated with at least all devices of the group;

14

exposing the set of second level commands in the command base that are common to all devices in the group of devices to enable the network management station to avoid errors from incompatible commands being individually applied to at least one device in the group of devices;

receiving a selection from the set of second level commands in the command base;

automatically executing the command to perform a management operation on each network device in the group of devices;

wherein the management operation is compatible with any device in the group of devices.

17. The system of claim **16**, wherein the management operation comprises displaying a list of devices that are contained in the group.

18. The system of claim **16**, wherein the management operation comprises configuring a plurality of interfaces that are implemented by a plurality of selected devices.

19. The system of claim **16**, wherein the management operation comprises displaying one or more alarms that are generated only by devices in the group, wherein a network device that is not in the group generates an alarm, and the alarm generated by the network device that is not in the group is not displayed.

20. The system of claim **16**, wherein the management operation comprises displaying one or more events that are generated only by devices in the group, wherein a network device that is not in the group of devices generates an event, and the event generated by the network device that is not in the group is not displayed.
